
Dodge Construction Network Code Price List & Estimating Matrix (v3.2)

Sample matrix summary · Square foot, unit and DOT mile-marker costing

This summary mirrors the sample Excel model. It shows how one consistent code price method values a project from public planning data. All quantities are placeholders and all rates are example figures, not an official price list.

1. Square Foot Method

Extended cost = quantity (SF) x unit cost (\$/SF). Used for building types valued by area.

Item	Quantity	Unit	Unit cost	Extended cost
Barn	10,000	SF	\$30	\$300,000
Hangar	20,000	SF	\$100	\$2,000,000

2. Unit Valuation

Extended cost = quantity x unit cost. Used for equipment valued per each.

Item	Quantity	Unit	Unit cost	Extended cost
Commercial boiler	1	EA	\$500,000	\$500,000
Air handling unit (AHU)	1	EA	\$150,000	\$150,000

3. DOT Mile-Marker Linear Costing

Miles = [end mile marker - start mile marker]. Cost = miles x per-mile rate. The sample file leaves the per-mile rate blank for you to enter, so the example segment (marker 10 to marker 15, 5 miles) shows \$0 until a rate is supplied.

4. Assumptions & Sources

Quantities are placeholders. Rates are example figures supplied by the site owner. Replace the inputs in the Excel model (blue cells; yellow cells need a value) to value a real project. Record the source document and assumptions for every figure.

Sample total with placeholder inputs: \$2,950,000 (square foot and unit rows only).
